Introduction

The functors $K_1, K_2$ for a commutative field $k$ are closely related to the theory of the general linear group via exact sequences of groups

$$1 \to \text{SL}(k) \to \text{GL}(k) \xrightarrow{\det} K_1(k) \to 1,$$

$$1 \to K_2(k) \to \text{St}(k) \to \text{SL}(k) \to 1.$$

Here the groups $\text{GL}(k), \text{SL}(k)$ are inductive limits of the well known matrix groups of the general and special linear group over $k$ with $n$ rows and columns: $\text{GL}(k) = \lim \text{GL}_n(k), \text{SL}(k) = \lim \text{SL}_n(k),$ and $K_1(k) \cong k^\ast,$ the latter denoting the multiplicative group of $k.$

The groups $\text{SL}_n(k), \text{SL}(k)$ are all perfect, i.e., equal to their commutator subgroups. It is known that any perfect group $G$ has a universal central extension $\tilde{G},$ i.e., there is an exact sequence of groups

$$1 \to A \to \tilde{G} \to G \to 1$$

such that $A$ embeds into the center of $\tilde{G},$ and such that any such central extension factors from the above sequence. The universal central extension sequence and in particular its kernel $A$ is unique for $G$ up to isomorphism, and the abelian group $A$ is called the fundamental group of $G$ – see Thm. 1.1 ii) and subsequent Remark 1.

The Steinberg group $\text{St}(k)$ in the second exact sequence above is the universal central extension of $\text{SL}(k)$ and $K_2(k)$ is its fundamental group.

Similarly, the universal central extension of $\text{SL}_n(k)$ is denoted by $\text{St}_n(k)$ and called the Steinberg group of $\text{SL}_n(k).$ Again there are central extensions

$$1 \to K_2(n,k) \to \text{St}_n(k) \to \text{SL}_n(k) \to 1$$

and the group $K_2(n,k)$ is the fundamental group of $\text{SL}_n(k).$

One has natural epimorphisms $K_2(n,k) \to K_2(k)$ for $n \geq 2,$ which are isomorphisms for $n \geq 3,$ but the latter is not true in general for $n = 2.$ The groups $K_2(n,k)$ can be described in terms of so-called symbols, i.e., generators indexed by pairs of elements from $k^\ast$ and relations reflecting the

\[\text{cf. the first lecture by Eric Friedlander}\]

\[\text{except for (very) small fields } k \text{ and small } n, \text{ see Thm. 2.1 below}\]
additive and multiplicative structure of the underlying field \( k \). This is the content of a theorem by Matsumoto (Thm. 2.2).

The proof of this theorem makes heavy use of the internal group structure of \( \text{SL}_n(k) \). However, the group \( \text{SL}_n(k) \) is a particular example of the so-called “Chevalley groups” over the field \( k \), which are perfect and have internal structures quite similar to those of \( \text{SL}_n(k) \).

In full generality, the theorem of Matsumoto describes “\( k \)-theoretic” results for all Chevalley groups over arbitrary fields (Thm. 5.2).

Among these groups, there are, e.g., the well known symplectic and orthogonal groups, and their corresponding groups of type \( K_2 \) are closely related to each other and to the powers of the fundamental ideal of the “Witt ring” of the underlying field – which play important roles in the context of quadratic forms (see the lectures given by Alexander Vishik) and in the context of the Milnor conjecture and, more generally, the Bloch–Kato conjecture (see the lectures given by Charles Weibel).

Our lectures are organized as follows:

In section 1, we reveal the internal structure of \( \text{SL}_n(k) \) together with a theorem by Dickson and Steinberg which gives a presentation of \( \text{SL}_n(k) \) and its universal covering group in terms of generators and relations (Thm. 1.1). We formulate the theorem by Matsumoto for \( \text{SL}_n(k) \) (Thm. 1.2). In an appendix, in order to prepare for the general cases of Chevalley groups, we discuss the so-called “root system” of \( \text{SL}_n(k) \) in explicit terms.

In section 2, we outline the basic notions for the theory of linear algebraic groups, in particular, we discuss tori, Borel subgroups and parabolic subgroups.

In section 3, the notion of root systems is discussed, in particular, root systems of rank one and two are explicitly given, as they are important ingredients for the formulation of the theorems by Steinberg and Matsumoto for Chevalley groups. The classification of semi-simple algebraic groups over algebraically closed fields is given, Chevalley groups over arbitrary fields are described including their internal structure theorems (Thm. 3.3).

In section 4, the theorems by Steinberg and by Matsumoto for Chevalley groups are given (Thm. 4.1, Thm. 4.2), and relations between their associated “\( K_2 \)”–type groups are explained.

In section 5, we go beyond Chevalley groups and describe the classification and structure of almost simple algebraic groups (up to their so-called
“anisotropic kernel”), in terms of their Bruhat decomposition (relative to their minimal parabolic subgroups) and their Tits index (Thm. 5.2).

In section 6, we describe some $K$-theoretic results for almost simple algebraic groups which are not Chevalley groups, mostly for the group $SL_n(D)$, where $D$ is a finite dimensional central division algebra over $k$ (Thms. 6.1, 6.2, 6.3, 6.4, 6.5, 6.6), and finally formulate several open questions.

1 The group structure of $SL_n$ over a field

Let $k$ be any field. By $k^*$, we denote the multiplicative group of $k$.

We consider the groups of matrices

$$
\begin{align*}
GL_n(k) &= \{ (a_{kl}) \in M_n(k) \mid 1 \leq k, l \leq n, \det(a_{kl}) \neq 0 \} \\
G := SL_n(k) &= \{ (a_{kl}) \in GL_n(k) \mid \det(a_{kl}) = 1 \}.
\end{align*}
$$

The determinant map $\det : GL_n(k) \to k^*$ yields an exact sequence of groups:

$$1 \to SL_n(k) \to GL_n(k) \to k^* \to 1.$$

Let $e_{ij} := (a_{kl})$ be the matrix with coefficients in $k$ such that $a_{kl} = 1$ if $(k, l) = (i, j)$ and $a_{kl} = 0$ otherwise, and let $1 = 1_n \in GL_n(k)$ denote the identity matrix.

We define, for $x \in k$ and $i, j = 1, \ldots, n$, $i \neq j$, the matrices

$$
\begin{align*}
&u_{ij}(x) = 1_n + xe_{ij} \quad (x \in k) \\
&w_{ij}(x) = u_{ij}(x) u_{ji}(-x^{-1}) u_{ij}(x) \quad (x \in k, x \neq 0) \\
&h_{ij}(x) = w_{ij}(x) w_{ij}(-1) \quad (x \in k, x \neq 0).
\end{align*}
$$

The matrices $w_{ij}(x)$ are monomial, and the matrices $h_{ij}(x)$ are diagonal.

(Recall that a monomial matrix is one which has, in each column and in each line, exactly one non-zero entry.)

**Example:** For $n = 2$, we have:

$$
\begin{align*}
u_{12}(x) &= \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix}, & w_{12}(x) &= \begin{pmatrix} 0 & x \\ -x^{-1} & 0 \end{pmatrix}, & h_{12}(x) &= \begin{pmatrix} x & 0 \\ 0 & x^{-1} \end{pmatrix}, \\
u_{21}(x) &= \begin{pmatrix} 1 & 0 \\ x & 1 \end{pmatrix}, & w_{21}(x) &= \begin{pmatrix} 0 & -x^{-1} \\ x & 0 \end{pmatrix}, & h_{21}(x) &= \begin{pmatrix} x^{-1} & 0 \\ 0 & x \end{pmatrix}.
\end{align*}
$$
For \( n \geq 2 \) we obtain matrices with entries which look, at positions \( ii, ij, ji, jj \), the same as the matrices above at positions \( 11, 12, 21, 22 \) respectively, and like the unit matrix at all other positions.

The proof of the following is straightforward:

(1) The group \( \text{SL}_n(k) \) is generated by the matrices \( \{ u_{ij}(x) \mid 1 \leq i, j \leq n, \, i \neq j, \, x \in k \} \)

(2) The matrices \( \{ w_{ij}(x) \mid 1 \leq i, j \leq n, i \neq j, x \in k^* \} \) generate the subgroup \( N \) of all monomial matrices of \( G \).

(3) The matrices \( \{ h_{ij}(x) \mid 1 \leq i, j \leq n, i \neq j, x \in k^* \} \) generate the subgroup \( T \) of all diagonal matrices of \( G \).

The group \( N \) is the normalizer of \( T \) in \( G \), and the quotient \( W := N/T \) is isomorphic to the symmetric group \( \mathfrak{S}_n \), i.e., the group of permutations of the \( n \) numbers \( \{ 1, \ldots, n \} \).

This isomorphism is induced by the map

\[
\sigma : N \to \mathfrak{S}_n, \quad w_{ij}(x) \mapsto (ij),
\]

where \( (ij) \) denotes the permutation which interchanges the numbers \( i, j \), leaving every other number fix.

For the elements \( u_{ij}(x), \, w_{ij}(x), \, h_{ij}(x) \) we have the following relations:

(A) \( u_{ij}(x + y) = u_{ij}(x) \, u_{ij}(y) \)

(B) \[
[u_{ij}(x), u_{kl}(y)] = \begin{cases} 
  u_{lj}(xy) & \text{if } i \neq l, j = k, \\
  u_{jk}(-xy) & \text{if } i = l, j \neq k, \\
  1 & \text{otherwise, provided } (i, j) \neq (j, i)
\end{cases}
\]

(B’) \( w_{ij}(t) \, u_{ij}(x) \, w_{ij}(t)^{-1} = u_{ji}(-t^{-2}x), \) for \( t \in k^*, x \in k \).

(C) \( h_{ij}(xy) = h_{ij}(x) \, h_{ij}(y) \)

Remarks:

- The relation (B) is void if \( n = 2 \).
- If \( n \geq 3 \), the relations (A), (B) imply the relation (B’).
We denote by $B$ and $U$ the subgroups of $G$ defined by

$$
B = \left\{ \begin{pmatrix} \star & \star & \star \\ \vdots & \ddots & \star \\ 0 & \cdots & \star \end{pmatrix}, \text{upper triangular} \right\},
$$

$$
U = \left\{ \begin{pmatrix} 1 & \star & \star \\ \vdots & \ddots & \star \\ 0 & \cdots & 1 \end{pmatrix}, \text{unipotent upper triangular} \right\}
$$

Then:

i) The group $B$ is the semi-direct product $T \ltimes U$ with normal subgroup $U$.

ii) The subgroup $B$ is a maximal connected solvable subgroup of $G$, it is the stabilizer group of the canonical maximal flag of vector spaces.

$$
0 \subset k \subset k^2 \subset \ldots \subset k^{n-1} \subset k^n.
$$

iii) The quotient $G/B$ is a projective variety.

iv) Any subgroup $P$ of $G$ containing $B$ is the stabilizer group of a subflag of the canonical maximal flag. $0 \subset k \subset k^2 \subset \ldots \subset k^{n-1} \subset k^n$. In this case $G/P$ is projective variety.

v) Every subgroup of $G$ which is the stabilizer of some flag of vector spaces is conjugate to such a $P$ as in iv).

vi) We have a so-called Bruhat decomposition: $G = BNB = \cup_{w \in W} B\tilde{w}B$ into disjoint double cosets $B\tilde{w}B$ where $\tilde{w}$ is a pre-image of $w$ under $N \to W$. Since $T \subset B$, the double coset $B\tilde{w}B$ does not depend on the choice of the pre-image $\tilde{w}$ for $w \in W$, hence we may denote this double coset by $BwB$. Therefore we may write the Bruhat decomposition as $G = BNB = \cup_{w \in W} BwB$.

Proof: i) As a consequence of the relations (A), (B) resp. (B'), we have the following relations:
This shows that $U$ is normalized by $T$, and it is obvious that $U \cap T = \{1\}$ ii), iii) (Cf. [24], 6.2)

iv), v), vi) The proofs here are an easy exercise and recommended as such, if you are a beginner in this subject and want to gain some familiarity with the basics.

**Examples:**

- If $n = 2$, we have $W \cong S_2 \cong \mathbb{Z}/2\mathbb{Z}$ and $G = B \cup B \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right) B$

- If $n = 3$, we have $W \cong S_3$. For shortness, we write $w_{ij} := w_{ij}(1)$, then we get:

$$w_{12} = \left( \begin{array}{ccc} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{array} \right), \quad w_{13} = \left( \begin{array}{ccc} 0 & 0 & 1 \\ 0 & 1 & 0 \\ -1 & 0 & 0 \end{array} \right), \quad w_{23} = \left( \begin{array}{ccc} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{array} \right),$$

$$w_{12} w_{13} = \left( \begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & -1 \\ -1 & 0 & 0 \end{array} \right), \quad (w_{12} w_{13})^2 = \left( \begin{array}{ccc} 0 & 0 & -1 \\ 1 & 0 & 0 \\ 0 & -1 & 0 \end{array} \right).$$

The permutations associated to these elements are given by

$$w_{ij} \mapsto (ij), \quad w_{12} w_{13} \mapsto (132), \quad (w_{12} w_{13})^2 \mapsto (123),$$

and the Bruhat decomposition is given by

$$G = B \cup B w_{12} B \cup B w_{13} B \cup B w_{23} B \cup B w_{12} w_{13} B \cup B (w_{12} w_{13})^2 B$$

**Theorem 1.1** (Dickson, Steinberg, cf. [25], Thm. 3.1 ff., Thm. 4.1 ff.)
i) A presentation of $G$ is given by
(A), (B), (C) if $n \geq 3$, and
(A), (B'), (C) if $n = 2$.

ii) Denote by $\tilde{G}$ the group given by the presentation
(A), (B) if $n \geq 3$, and
(A), (B') if $n = 2$.

Then the canonical map $\pi : \tilde{G} \to G$ is central, which means that its kernel is contained in the center of $\tilde{G}$.

Assume $|k| > 4$ if $n \geq 3$ and $|k| \neq 4, 9$ if $n = 2$. Then this central extension is universal, which means: Every central extension $\pi_1 : G_1 \to G$ factors from $\pi$, i.e., there exists $g : \tilde{G} \to G_1$ such that $\pi = \pi_1 \circ g$.

Remark 1: As $G$ and $\tilde{G}$ are perfect, $\tilde{G}$ as a universal central extension of $G$ is unique up to isomorphism. The group $\text{St}_n(k) := \tilde{G}$ is called the Steinberg group of $\text{SL}_n(k)$.

Remark 2: If $k$ is finite field, then $G$ and $\tilde{G}$ equal. (This is proved in [25] as well.)

Remark 3: By the definition of $\tilde{G}$ and $G$, the elements $h_{ij}(xy)h_{ij}(x)^{-1}h_{ij}(y)^{-1}$ generate the kernel of $\pi : \tilde{G} \to G$.

**Theorem 1.2** (Matsumoto, cf. [12], Thm. 5.10, Cor. 5.11, see also Moore [16]) Let the notations and assumptions be the same as in the preceding theorem.

The elements $c_{ij}(x, y) := h_{ij}(x)h_{ij}(y)h_{ij}(xy)^{-1}, x, y \in k^*$ yield the relations $c_{ij}(x, y) = c_{ji}(y, x)^{-1}$ for $n \geq 2$, and are independent of $i, j$ for $n \geq 3$.

Let $c(x, y) := c_{12}(x, y)$. These elements fulfill the following relations:

$n = 2:$ (cf. [12], Prop. 5.5)
- (S1) $c(x, y) c(xy, z) = c(x, yz) c(y, z)$
- (S2) $c(1, 1) = 1$, $c(x, y) = c(x^{-1}, y^{-1})$
- (S3) $c(x, y) = c(x, (1 - x)y)$ for $x \neq 1$

$n \geq 3:$ (cf. [12], Lemme 5.6)
- (S^o1) $c(x, yz) = c(x, y) c(x, z)$
- (S^o2) $c(xy, z) = c(x, z) c(y, z)$
- (S^o3) $c(x, 1 - x) = 1$ for $x \neq 1$
In case $n = 2$, define $c^\ast(x, y) := c(x, y^2)$. Then $c^\ast(x, y)$ fulfills the relations $(S^o1)$, $(S^o2)$, $(S^o3)$.

Moreover, $\ker \pi : \tilde{G} \to G$ is isomorphic to the abelian group presented by

$$(S1), (S2), (S3) \quad \text{in case } n = 2$$

$$(S^o1), (S^o2), (S^o3) \quad \text{in case } n \geq 3$$

Remarks:

i) The relations $(S1)$, $(S2)$, $(S3)$ are consequences of the relations $(S^o1)$, $(S^o2)$, $(S^o3)$.

ii) A map $c$ from $k^\ast \times k^\ast$ to some abelian group is called a Steinberg cocycle (resp. a Steinberg symbol), if it fulfills relations $(S1)$, $(S2)$, $(S3)$ (resp. $(S^o1)$, $(S^o2)$, $(S^o3)$).

iii) The relations $(S^o1)$, $(S^o2)$ say that $c$ is bimultiplicative, and hence the group presented by $(S^o1)$, $(S^o2)$, $(S^o3)$ can be described by $k^\ast \otimes_{\mathbb{Z}} k^\ast / \langle x \otimes (1 - x) \mid x \in k^\ast, x \neq 1 \rangle$.

iv) $\ker \pi : \text{St}_n(k) \to \text{SL}_n(k)$ is denoted by $K_2(n, k)$. Clearly we have homomorphisms

$$K_2(2, k) \to K_2(3, k) \to K_2(4, k) \to \ldots \to K_2(n, k), \quad (n \geq 3),$$

hence the inductive limit

$K_2(k) := \lim_{\to} K_2(n, k)$ is defined and isomorphic to $K_2(n, k)$ for $n \geq 3$.

The elements of $K_2(k)$ are generated by the Steinberg symbols, very often (in particular in the context of $K$-theory) denoted by $\{x, y\} := c(x, y)$.

The "Theorem of Matsumoto" very often is just quoted as the fact that, for any field $k$, the abelian group $K_2(k)$ is presented by the generators $\{x, y\}$, $x, y \in k^\ast$, subject to relations

$$\{x, yz\} = \{x, y\}\{x, z\}, \quad \{xy, z\} = \{x, z\}\{y, z\},$$

and

$$\{x, 1 - x\} = 1 \text{ for } x \neq 1.$$
This does not just hold for $K_2(k)$, but as well for all $K_2(n,k)$, $n \geq 3$. For this (restricted) statement, there is a complete and elementary proof in the book on “Algebraic K-Theory” by Milnor (cf. [15], §§ 11, 12, pages 93–122).

However, this neither does include the case of $K_2(2,k)$, nor the much wider cases of arbitrary simple “Chevalley groups”, which were treated by Matsumoto’s article as well. We will see more of this in the following sections; in particular we will see that the kernel of the surjective map

$$K_2(2,k) \to K_2(n,k) \to K_2(k) \ (n \geq 3),$$

can be described, by a result of Suslin [28], in a satisfying way in terms of other invariants of the underlying field $k$.

**Appendix of section 1: A first digression on root systems**

We will exhibit here the root system of $G = \text{SL}_n$ as a first example, in spite of the fact that the formal definition of a “root system” will be given in a later talk.

For this we let $\text{Diag}_n(k)$ denote the subgroup of all diagonal matrices in $\text{GL}_n(k)$, and we denote a diagonal matrix just by its components:

$$\text{diag}(d_\nu) = \text{diag}(d_1, \ldots, d_n) := \begin{pmatrix} d_1 & \ldots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \ldots & d_n \end{pmatrix} \in \text{Diag}_n.$$

Clearly $T \subset \text{Diag}_n(k)$. For $i = 1, \ldots, n$ we define homomorphisms:

$$\varepsilon_i : \text{Diag}_n(k) \to k^* \text{ by } \varepsilon_i(\text{diag}(d_\nu)) = d_i.$$

$\{\varepsilon_i\}$ is a basis of the (additively written) free $\mathbb{Z}$-module $X(\text{Diag}_n)$ of all characters (i.e., homomorphisms) $\chi : \text{Diag}_n \to k^*$: In general, such a character is given by

$$\chi(\text{diag}(d_\nu)) = \prod_{i=1}^n d_i^{n_i}, \text{ with } n_i \in \mathbb{Z} \text{ for } i = 1, \ldots, n,$$

hence we have $\chi = \sum_{i=1}^n n_i \varepsilon_i$, and $\chi$ vanishes on $T$ if and only if $n_1 = \ldots = n_n$. Hence the set $\{\alpha_i := \varepsilon_i - \varepsilon_{i+1} \mid i = 1, \ldots, n - 1\}$ is a basis of the $\mathbb{Z}$-module $X(T)$ of all characters on $T$. 
The group $W = N/T$ operates on $X(\text{Diag}_n(k))$ by
\[ (^{w}\chi)(d) := \chi(\tilde{w}d\tilde{w}^{-1}) \text{ for all } d \in \text{Diag}_n(k), w \in N/T, \]
where $\tilde{w} \in N$ is any pre-image of $w$. (This is unique modulo $T$, hence $\tilde{w}d\tilde{w}^{-1}$ is independent of its choice.)

Exercise: If $d = \text{diag}(d_\nu)$, then $(^{w}\chi)(\text{diag}(d_\nu)) = \text{diag}(w^{\nu})$. (Hint: Use $W = S_n$.)

The submodule $X(T)$ (as well as $Z(\varepsilon_1 + \ldots + \varepsilon_n)$) is invariant under $W$.

On the $\mathbb{R}$-vector space $X(\text{Diag}_n(k)) \otimes_{\mathbb{Z}} \mathbb{R}$, we consider the scalar product $\langle , \rangle$ which has $\varepsilon_i$ as an orthonormal basis (we identify the elements $\chi \in X(\text{Diag}_n(k)) \otimes_{\mathbb{Z}} \mathbb{R}$). This scalar product is invariant with respect to the operation of $W$, as $^{w}\varepsilon_i = \varepsilon_{w(i)}$.

For the basis $\alpha_i = \varepsilon_i - \varepsilon_{i+1}$ of the $\mathbb{R}$-vector space $V := X(T) \otimes_{\mathbb{Z}} \mathbb{R}$, we obtain the following orthogonality relations:

\[ \langle \alpha_i, \alpha_j \rangle = \langle \varepsilon_i, \varepsilon_j \rangle - \langle \varepsilon_i, \varepsilon_{j+1} \rangle - \langle \varepsilon_{i+1}, \varepsilon_j \rangle + \langle \varepsilon_{i+1}, \varepsilon_{j+1} \rangle = \begin{cases} 2 & \text{if } j = i, \\ -1 & \text{if } |j - i| = 1, \\ 0 & \text{if } |j - i| > 1. \end{cases} \]

This means that all $\alpha_i$ are of same length $\sqrt{2}$, and the angle between two distinct elements $\alpha_i, \alpha_j, i \neq j$ of them has cosine

\[ \langle \alpha_i, \alpha_j \rangle / 2 = \begin{cases} -1/2 & \text{if } |j - i| = 1 \\ 0 & \text{if } |j - i| > 1 \end{cases} \]

which means that the angle between them is either $\pi/3$ or $\pi/2$.

Define $\Sigma = \{ \alpha_{i,j} := \varepsilon_i - \varepsilon_j \mid 1 \leq i, j \leq n, i \neq j \}$ (hence $\alpha_{i,i+1} = \alpha_i$).

This finite set is, as a subset of $V = X(T) \otimes_{\mathbb{Z}} \mathbb{R}$, invariant under $W$, and symmetric, i.e., $\Sigma = -\Sigma$.

Clearly,
\[ \alpha_{ij} = \begin{cases} \alpha_i + \alpha_{i+1} + \ldots + \alpha_{j-1} & \text{if } i < j \\ -\alpha_j - \alpha_{j+1} - \ldots - \alpha_{i-1} & \text{if } i > j \end{cases} \]

hence every element in $\Sigma$ is an integral linear combination of the $\alpha_i$ with coefficients of the same sign.

For $n = 3$, we obtain $\Sigma = \{ \pm\alpha_1, \pm\alpha_2, \pm(\alpha_1 + \alpha_2) = \pm\alpha_{13} \}$, and the geometric realization looks as follows:
**Root system of** $\text{SL}_3(k)$:

In particular, every pair $(i,j)$ of indices with $i \neq j$ (i.e., off-diagonal matrix positions in $\text{SL}_n(k)$) determines a root $\alpha_{ij} = e_i - e_j \in \Sigma$.

Using this correspondence, we can write the formulae $(H)$ in a completely uniform way:

$$h_{ij}(t) \ u_{kl}(x) \ h_{ij}(t)^{-1} = u_{kl}(\ t^{(\alpha_{ij}, \alpha_{kl})} \ x)\ . \quad (1)$$

We leave the proof of this interesting fact as an exercise to the reader.

# 2 Linear algebraic groups over fields

The basic language for algebraic groups is that of algebraic geometry. An algebraic $k$-group $G$ over a field $k$ is an algebraic $k$-variety, which we won’t define here formally. We here will just think of them as the set $G(K)$ of common solutions of one or more polynomials with coefficients in $k$, as in the easy example of $\text{SL}_n(k)$, which can be considered as the set of zeros $x = (x_{ij}) \in k^{n^2}$ of the polynomial equation $\det(x) - 1 = 0$. Clearly, if $k'/k$ is a field extension (or even a commutative ring extension), then we may as well consider the solutions of the same set of polynomials, but over $k'$ rather than over $k$, and we will denote those by $G(k')$. Solutions over $k'$ are called the $k'$-rational points of $G$.

By $k$-morphisms between such varieties we will mean mappings which are given by polynomials with coefficients in $k$.

For example, $\det : \text{GL}_n(k) \to k^*$ is such a $k$-morphism – which at the same time is a homomorphism of groups as well.

For more details concerning the algebraic geometry needed for our topic see [24], chap. 1.
Definition 2.1 A linear algebraic $k$-group is an affine $k$-algebraic variety $G$, together with $k$-morphisms $(x, y) \mapsto xy$ of $G \times G$ into $G$ ("multiplication") and $x \mapsto x^{-1}$ of $G$ into $G$ ("inversion") such that the usual group axioms are satisfied, and such that the unit element $1$ is $k$-rational.

This definition makes $G(k')$ a group for every extension field (or commutative ring) $k'/k$.

Since every polynomial over $k$ is as well a polynomial over $k'$, an algebraic group $G$ over $k$ becomes an algebraic group over $k'$ in a natural way, this is denoted by $G \times_k k'$ and is said to be obtained from $G$ by field extension with $k'$. Similarly for varieties in general.

The notions “linear algebraic group” and “affine algebraic group” are synonymous: every algebraic group which is an affine variety can be embedded by a $k$ morphism as a closed $k$-subgroup into some $GL_n$ ([24], 2.3.7).

There is a broader notion of algebraic groups, but here we will restrict to the linear or affine case.

In the following we will make the convention: The notion “$k$-group” will always mean “linear algebraic $k$-group”; an “algebraic $k$-subgroup” of a $k$-group $G$ will mean an algebraic $k$-group which is a $k$-subvariety of $G$. A homomorphism of $k$-groups is a $k$-morphism of algebraic varieties which induces a group homomorphism for the corresponding groups of rational points.

Examples:

- The linear $k$-group $GL_n$, defined by

  $GL_n(k) = \{ (x_{ij}, y) \in k^{n^2+1} \mid \det(x_{ij}) \cdot y = 1 \}$

  Clearly, multiplication and inversion are given by the usual matrix operations, which are “polynomially” defined over any field.

  (As the usual condition $\det(x_{ij}) \neq 0$ is not a polynomial equation, we need the additional coordinate $y$ to describe $GL_n$ as an algebraic variety.)

- A $k$-subgroup of $GL_n(k)$ is $SL_n$, defined by

  $SL_n(k) = \{ (x_{ij}) \in GL_n(k) \mid \det(x_{ij}) - 1 = 0 \}$.
• The “additive group” $G_a$ is defined by $G_a(k) = k$. Here the defining polynomial is just the zero polynomial. Multiplication and inversion are given by the additive group structure of $k$.

• The “multiplicative group” is given by $G_m = GL_1$. We have $G_m(k) = \{ (x, y) \in k^2 \mid x \cdot y = 1 \}$.

• Let $q$ be a regular quadratic form on $k$-vector space $V$ of finite dimension $n$. Then we have its associated (or polar) bilinear form by $\langle x, y \rangle = q(x + y) - q(x) - q(y)$ for $x, y \in V$.

For a basis $e_1, \ldots, e_n$ of $V$, the form $q$ is represented by the symmetric matrix $A = (\langle e_i, e_j \rangle)_{i,j=1,\ldots,n} \in GL_n(k)$. The groups defined by $O_q(k) = \{ x \in GL_n(k) \mid xA x^t - A = 0 \}$ and $SO_q(k) = \{ x \in GL_n(k) \mid xA x^t - A = 0, \det x - 1 = 0 \}$ are $k$-groups, called the orthogonal (resp. special orthogonal) group of the quadratic form $q$.

• The symplectic group $Sp_{2n}(k)$ is defined by $Sp_{2n}(k) = \{ x \in GL_{2n}(k) \mid xJ x^t = J \}$ where $J = \begin{pmatrix} 0 & 1_n \\ 1_n & 0 \end{pmatrix} \in GL_{2n}(k)$.

Remark: For algebraic groups as varieties, the notions “connectedness” and “irreducibility” coincide. The connected component of an algebraic $k$-group $G$ containing the unit element is often called its 1-component and denoted by $G^0$.

The 1-connected component of $k$-group is a closed normal $k$-subgroup of finite index, and every closed $k$-subgroup of finite index contains the 1-component ([24], 2.2.1).

Examples:

• $GL_n, SL_n, SO_q, Sp_{2n}(k), G_a, G_m$ are connected ([24], 2.2.3).

• The 1-connected component of $O_q$ is $SO_q$: we have a decomposition into two components $O_q(k) = SO_q(k) \cup O_q^-(k)$ with $O_q^-(k) = \{ x \in O_q(k) \mid \det x+1 = 0 \}$. (Clearly, $O_q^-$ is not a group, but a coset in $O_q$.)
Many concepts of abstract groups (the notion “abstract” used here as opposed to “algebraic” groups) can be transferred to algebraic groups: Very often, if subgroups are concerned, one has to use the notion of “closed subgroups” which are closed as subvarieties.

For example, if $H, K$ are closed $k$-subgroups of a $k$-group $G$, then the subgroup $[H, K]$ generated by the commutators $[x, y] = x y x^{-1} y^{-1}$ with $x \in H(k)$, $y \in K(k)$ (more precisely, the Zariski closure of these) is a $k$-subgroup of $G$ ([24], 2.2.8).

In this sense, the sequence $G^{(0)} = G, G^{(1)} = [G, G], \ldots, G^{(i+1)} := [G^{(i)}, G^{(i)}], \ldots$ of $k$-subgroups of $G$ is well defined, and $G$ is called solvable if this sequence becomes trivial after a finite number of steps.

There is also the concept of quotients: If $H$ is a closed $k$-subgroup of the linear $k$-group $G$, then there is an essentially unique “quotient $k$-variety” $G/H$ which is an affine $k$-group in case $H$ is normal, but, as a variety, it is in general not affine (cf. [24], 5.5.5, 5.5.10 for algebraically close fields, and 12.2.1, 12.2.2 in general).

As an example for the latter fact, we look at $G = \text{SL}_2$ and $H$ the $k$-subgroup of upper triangular matrices. Then $G/H$ is isomorphic to the projective line $\mathbb{P}^1$, since $H$ is the stabilizer subgroup of a line in $k^2$, and $G$ operates transitively on all lines in $k^2$.

A linear algebraic $k$-group $T$ is called a $k$-torus, if, over an algebraic closure $\overline{k}$, the group $T(\overline{k})$ becomes isomorphic to a (necessarily finite) product of copies of groups $G_m(\overline{k})$.

A $k$-groups is called unipotent, if, after some embedding into some $\text{GL}_n$, every element becomes a unipotent matrix (i.e., a matrix with all eigenvalues equal to 1). It can be shown that this condition is independent of the embedding.

An example is the $k$-group of strictly upper diagonal matrices in $\text{GL}_n$.

The overall structure for connected linear algebraic groups over a perfect field $k$ can be described as follows:

i) $G$ has a unique maximal connected linear solvable normal $k$-subgroup $G_1 =: \text{rad } G$, which is called the radical of $G$. The quotient group $G/G_1$ is semisimple, i.e., its radical is trivial.

ii) $G_1$ has a unique maximal connected normal unipotent $k$-subgroup $G_2 =: \text{rad}_u G$, which is called the unipotent radical of $G$. The quotient
$G_1/G_2$ is a $k$-torus, the quotient $G/G_2$ is a reductive $k$-group, i.e., it is an almost direct product of a central torus $T$ and a semisimple group $G'$. (The notion “almost direct product” means that $G = T \cdot G'$ and $T \cap G'$ is finite.)

Let us summarize these facts in a table (recall that $k$ is perfect here):

<table>
<thead>
<tr>
<th></th>
<th>conn. (normal)</th>
<th>conn. (normal)</th>
<th>conn. unipotent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Groups:</td>
<td>$G$ $\triangleright$ $G_1 = \text{rad } G$ $\triangleright$ $G_2 = \text{rad}_u G$</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Quotient:</td>
<td>$G/G_1$ \hspace{1cm} semisimple</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>$G_1/G_2$ \hspace{1cm} torus</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Quotient:</td>
<td>$G/G_2 = G' \cdot T$ \hspace{1cm} reductive, i.e., almost direct product of semisimple $G'$ with central torus $T$</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In particular, for a $k$-group $G$ the following holds:

i) $G$ is reductive if and only if $\text{rad}_u G = 1$

ii) $G$ is semisimple if and only if $\text{rad } G = 1$

For $\text{char } k = 0$ it is known that $\text{rad}_u G$ has a reductive complement $H$ such that $G = H \cdot \text{rad}_u G$ is a semidirect product.

Examples:

i) For $G = \text{GL}_n(k)$, $\text{rad } G = \text{center}(G)$ is isomorphic to $\mathbf{G}_m$, the group $G/\mathbf{G}_m$ is isomorphic to $\text{PGL}_n$, which is simple, and $\text{rad}_u (G) = 1$.

ii) Let $e_1, \ldots, e_n$ be the standard basis of $k^n$. For $r < n, s = n - r$, take

$$G = \text{Stab}(k e_1 \oplus \ldots \oplus k e_r) = \left\{ \begin{pmatrix} r & s \\ s & * \\ r & * \\ 0 & * \end{pmatrix} \in \text{GL}_n(k) \right\},$$

where $*$ represents any matrix.
where \( r, s \) indicate the number of rows and columns of the submatrices denoted by \( * \).

Then \( \text{rad} \ G, \ \text{rad}_u \ G \) are given, respectively, by the matrices of the shape

\[
\begin{pmatrix}
\alpha & \cdots & 0 \\
\vdots & \ddots & \vdots \\
0 & \cdots & \alpha \\
\beta & \cdots & 0 \\
\vdots & \ddots & \vdots \\
0 & \cdots & \beta \\
\end{pmatrix}
\quad \text{and} \quad
\begin{pmatrix}
1 & \cdots & 0 \\
\vdots & \ddots & \vdots \\
0 & \cdots & 1 \\
\beta & \cdots & 0 \\
\vdots & \ddots & \vdots \\
0 & \cdots & \beta \\
\end{pmatrix}
\]

Hence

\[
G/\text{rad}_u \ G \cong \text{GL}_r(k) \times \text{GL}_s(k) \\
G/\text{rad} \ G \cong \text{PGL}_r(k) \times \text{PGL}_s(k) \\
\text{rad} \ G/\text{rad}_u \ G \cong \text{G}_m \times \text{G}_m
\]

Remarks about Tori (cf. [24], chap.3, for proofs):

A linear \( k \)-group \( T \) is a \( k \)-torus if, over some algebraic field extension \( k'/k \), it becomes isomorphic to a (necessarily finite) product of multiplicative groups: \( T \times_k k' \cong \Pi \text{G}_m \).

If this holds, then in particular \( T \times_k k_s \cong \Pi \text{G}_m \) for a separable closure \( k_s \) of \( k \).

A \( k \)-torus \( T \) is said to be split if \( T \cong \Pi \text{G}_m \) (over \( k \). \( T \) is said to be anisotropic if it does not contain any split subtorus.

Example:

i) The algebraic \( \mathbb{R} \)-group \( T \) defined by

\[
T(\mathbb{R}) = \left\{ \begin{pmatrix} x & y \\ -y & x \end{pmatrix} \in \text{SL}_2(\mathbb{R}) \mid x^2 + y^2 = 1 \right\}
\]

is an anisotropic torus, since it is compact and hence cannot be isomorphic to \( \mathbb{R}^* \).

However, over \( \mathbb{C} \) it becomes

\[
T \times_{\mathbb{R}} \mathbb{C}(\mathbb{C}) = \left\{ \begin{pmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{pmatrix} \in \text{SL}_2(\mathbb{C}) \mid \lambda \neq 0 \right\} \cong \mathbb{C}^*
\]
This can be seen by making a suitable coordinate change (Exercise!). The group $T(\mathbb{R})$ can be considered as the group of norm-1-elements in $\mathbb{C}$.

ii) More generally, for any finite field extension $k'/k$, the group of norm-1-elements $\{x \in k'^* \mid N_{k'/k}(x) = 1\}$ is an anisotropic $k$-torus.

If $T$ is a $k$-torus, $k_s$ a separable closure of $k$, then the $\mathbb{Z}$-module of characters $X(T) = \text{Hom}_{k_s}(T, \mathbb{G}_m)$ is in fact a module over the Galois group $\Gamma := \text{Gal}(k_s/k)$.

We have:

- The group $X(T)$ is $\mathbb{Z}$-free-module and $T$ splits if and only if $\Gamma$ operates trivially on $X(T)$.
- The torus $T$ is anisotropic if and only if $X(T)^{\Gamma} = \{0\}$.
- There exist a unique maximal anisotropic $k$-subtorus $T_a$ of $T$, and a unique maximal split $k$-subtorus $T_s$ of $T$ such that $T_a \cdot T_s = T$ and $T_a \cap T_s$ is finite.

**Parabolic subgroups, Borel subgroups**, cf.\cite{24}, chap. 6

**Definition:** Let $G$ be connected linear $k$-group.

- A maximal connected solvable $k$-subgroup of $G$ is called a Borel subgroup of $G$.
- A $k$-subgroup of $G$ is called parabolic if it contains a Borel subgroup of $G$.

**Theorem 2.2** (Borel 1962)

Let $G$ be a connected $k$-group and $\bar{k}$ an algebraic closure of $k$.

- All maximal tori in $G$ are conjugate over $\bar{k}$. Every semisimple element of $G$ is contained in a torus; the centralizer of a torus in $G$ is connected.
- All Borel subgroups in $G$ are conjugate over $\bar{k}$. Every element of $G$ is in such a group.
Let $P$ a closed $k$-subgroup of $G$. The quotient $G/P$ is projective if and only if $P$ is parabolic. If $P$ is a parabolic subgroup of $G$, then it is connected and self-normalizing, i.e., equal to its normalizer subgroup $N_G(P)$ in $G$. If $P,Q$ are two parabolic subgroups containing the same Borel subgroup $B$ of $G$ and if they are conjugate, then $P = Q$.

**Example:** Let $G = \text{GL}_n$.

i) The $k$-subgroup $T = \text{Diag}_n$ of diagonal matrices is a maximal torus of $G$.

ii) The $k$-subgroup $B = \left\{ \begin{pmatrix} * & * & * \\ \vdots & * \\ 0 & * \end{pmatrix} \in \text{GL}_n \right\}$ of upper triangular matrices is a Borel subgroup of $G$.

iii) $P := \text{Stab}(ke_1) = \left\{ \begin{pmatrix} 1 & n-1 \\ n-1 & * \\ 0 & * \end{pmatrix} \in \text{GL}_n(k) \right\}$ contains the group $B$ of upper triangular matrices and is hence parabolic, and we have $G/P \cong \mathbb{P}^{n-1}$. (Here the numbers 1, $n-1$ again denote number of rows and columns.)

### 3 Root systems, Chevalley groups

**Root systems, definitions and basic facts:**

Good references for this subsection are [23], chap. V, and [6], chap. VI.

Let $V$ be a finite dimensional $\mathbb{R}$-vector space with scalar product $\langle \ , \ \rangle$. A set $\Sigma \subset V \setminus \{0\}$ is a root system in $V$ if the following statements i), ii), iii) hold:

i) The set $\Sigma$ is finite, generates $V$, and $-\Sigma = \Sigma$.

ii) For each $\alpha \in \Sigma$, the linear map $s_\alpha : V \rightarrow V$ defined by $s_\alpha(v) = v - 2\frac{\langle \alpha, v \rangle}{\langle \alpha, \alpha \rangle} \alpha$ leaves $\Sigma$ invariant: $s_\alpha(\Sigma) = \Sigma$.

iii) For each pair $\alpha, \beta \in \Sigma$, the number $n_{\beta, \alpha} = 2\frac{\langle \alpha, \beta \rangle}{\langle \alpha, \alpha \rangle}$ is an integer – a so-called “Cartan integer”.
Let $\Sigma$ be a root system on $V$.

$$\text{rank}(\Sigma) := \dim V$$ is called the rank of $\Sigma$.

$\Sigma$ is called reducible if there exist proper mutually orthogonal sub-spaces $V', V''$ of $V$ such that $V = V' \perp V''$ and $\Sigma = (V' \cap \Sigma) \cup (V'' \cap \Sigma)$. Otherwise $\Sigma$ is called irreducible.

$\Sigma$ is called reduced if $R_\alpha \cap \Sigma = \{ \pm \alpha \}$ for all $\alpha \in \Sigma$. (In general one has $R_\alpha \cap \Sigma \subset \{ \pm \alpha, \pm \alpha/2, \pm 2\alpha \}$.)

By definition, $s_\alpha$ is the reflection on the hyperplane $H_\alpha = R_\alpha^\perp$ of $V$ orthogonal to $\alpha$. The Weyl group $W(\Sigma)$ of $\Sigma$ is the subgroup of $\text{Aut}(V)$ generated by these reflections $\{ s_\alpha | \alpha \in \Sigma \}$.

A Weyl chamber of $\Sigma$ is a connected component of $V \setminus \cup_{\alpha \in \Sigma} H_\alpha$. The Weyl group acts simply transitive on all Weyl chambers. Each Weyl chamber $C$ defines an ordering of roots: $\alpha > 0$ if $(\alpha, v) > 0$ for every $v \in C$.

An element in $\Sigma$ is called a simple root (with respect to an ordering) if it is not the sum of two positive roots. Every root is an integral sum of simple roots with coefficients of same sign. The number of simple roots of $\Sigma$ with respect to any ordering is the same as $\dim V = \text{rank}(\Sigma)$, hence any set of simple roots forms a basis of $V$.

For the Cartan numbers one gets $n_{\beta,\alpha} n_{\alpha,\beta} = 4 \frac{(\alpha,\beta)^2}{(\alpha,\alpha)(\beta,\beta)} = 4 \cos^2 \varphi$, where $\varphi$ denotes the angle between $\alpha$ and $\beta$. As this is integral, only 8 angles are possible up to sign, and it is easily concluded that, for reduced root systems, only roots of up to two different lengths can occur. If $(\beta,\beta) \geq (\alpha,\alpha)$, then $(\beta,\beta) = p(\alpha,\alpha)$ with $p = 1, 2, 3$.

The Dynkin diagram of $\Sigma$ is a graph whose vertices are the simple roots, two vertices $\alpha, \beta$ with $p = \frac{(\beta,\beta)}{(\alpha,\alpha)} \geq 1$ are combined by $p$ edges, moreover, the direction of the smaller root is indicated by $<$ or $>$ in case $\alpha, \beta$ have different length.

The Dynkin diagrams classify the root systems uniquely. Below we list all reduced root systems of rank $\leq 2$ and their Dynkin diagrams.
Reduced root systems of rank \( \leq 2 \):

\[
W(A_1) = \mathbb{Z}_2, \text{ typical group: } \text{SL}_2, \text{ Dynkin diagram: } \circ_{\alpha}
\]

\[
W(A_1 \times A_1) = \mathbb{Z}_2, \text{ typical group: } \text{SL}_2 \times \text{SL}_2, \text{ Dynkin diagram: } \circ_{\alpha} \circ_{\beta}
\]

\[
W(A_2) = \mathbb{Z}_2, \text{ typical group: } \text{SL}_3, \text{ Dynkin diagram: } \circ_{\alpha} \circ_{\beta}
\]

\[
W(B_2) = \mathbb{Z}_2, \text{ typical group: } \text{SO}_5, \text{Sp}_4, \text{ Dynkin diagram: } \circ_{\alpha} \circ_{\beta}
\]

\[
W(G_2) = \mathbb{Z}_2, \text{ typical group: } \text{automorphism group of a Cayley algebra, Dynkin diagram: } \circ_{\alpha} \circ_{\beta}
\]

The Weyl groups of the rank 2 root systems are given by the presentation

\[
W = \langle s_{\alpha}, s_{\beta} \mid s_{\alpha}^2 = s_{\beta}^2 = (s_{\alpha} s_{\beta})^\kappa = 1 \rangle \text{ with } \kappa = 2, 3, 4, 6 \text{ respectively.}
\]
Root systems are, up to isometry, completely determined by their Dynkin diagrams and completely classified for arbitrary rank. Below we will give a complete list for the irreducible root systems.

**Root system of a semisimple $k$-group $G$**

Proofs for the facts given in the rest of this section can be found in the book by Springer [24], or also in the book by Borel [2].

Let $S \subset G$ be any $k$-torus.

The $k$-group $G$ operates on its Lie algebra $\mathfrak{g}$ by the adjoint representation $\text{Ad}_\mathfrak{g} : G \to \text{Aut} \mathfrak{g}$ (cf. [24], chap. 4.4).

Since $S$ contains only semisimple elements (which all commute with each other), it follows that $\text{Ad}_\mathfrak{g}(S)$ is diagonalizable. Hence $\mathfrak{g}$ can be decomposed into eigenspaces using characters $\alpha : S \to \mathbb{G}_m, \alpha \in X(S)$:

$$\mathfrak{g} = \mathfrak{g}_0^S \oplus \bigoplus_{\alpha \in X(S)} \mathfrak{g}_\alpha^S, \quad \mathfrak{g}_\alpha^S = \{ x \in \mathfrak{g} \mid \text{Ad}_\mathfrak{g}(s)(x) = \alpha(s)x \} \text{ for } \alpha \in X(S).$$

We denote the set of characters $\alpha$ which occur in the above decomposition by $\Sigma(G,T)$.

Assume now that $k$ is algebraically closed, i.e., $k = \bar{k}$. Then $G$ has a maximal split torus $T$. Since all such tori are conjugate in $G$, the set $\Sigma(G,T)$ is essentially independent of $T$ and is denoted by $\Sigma(G) = \Sigma(G,T)$, and is called “the” set of roots of $G$.

The normalizer $N = \text{Norm}_G T \subset G$ operates on the group of characters $X = X(T) = \text{Hom}(T, \mathbb{G}_m)$ (which is a free $\mathbb{Z}$-module of rank $= \dim T$). We choose a scalar product $\langle \cdot, \cdot \rangle$ on the $\mathbb{R}$-vector space $V = X \otimes_{\mathbb{R}} \mathbb{R}$ which is invariant under the (finite) group $W := N/T$.

Then the set $\Sigma := \Sigma(G)$ is a root system.

We choose an ordering (via some Weyl chamber), we also choose a set $\Delta \subset \Sigma$ of simple roots.

Then, by the preceding, we have $|\Delta| = \dim V = \dim T =: \text{rank} (G)$. (By definition, the rank of a semisimple group is the dimension of a maximal torus.)

The Dynkin diagram of $G$ is the Dynkin diagram of $\Sigma$.

Here we will give a list of all irreducible reduced root systems together
with the corresponding groups, insomuch they have special names. The number \( n \) will always denote the rank.

We have four infinite series \((A_n)_{n \geq 1}, (B_n)_{n \geq 2}, (C_n)_{n \geq 3}, (D_n)_{n \geq 4}\), and several “exceptional” root systems: \(E_6, E_7, E_8, F_4, G_2\).

Their Dynkin diagrams look as follows:

- **A\(_n\):**
  \[
  \begin{array}{c}
  \alpha_1 \quad \cdots \quad \alpha_n \\
  \end{array}
  \quad n \geq 1 \quad \text{SL}_{n+1}
  \]

- **B\(_n\):**
  \[
  \begin{array}{c}
  \alpha_1 \quad \cdots \quad \alpha_{n-1} \quad \alpha_n \\
  \end{array}
  \quad n \geq 2 \quad \text{SO}_{q_n}, \quad \text{dim } q = 2n+1
  \]

- **C\(_n\):**
  \[
  \begin{array}{c}
  \alpha_1 \quad \cdots \quad \alpha_{n-1} \quad \alpha_n \\
  \end{array}
  \quad n \geq 3 \quad C_2 \cong B_2 \quad \text{Sp}_{2n}
  \]

- **D\(_n\):**
  \[
  \begin{array}{c}
  \alpha_1 \quad \cdots \quad \alpha_{n-2} \quad \alpha_n \\
  \end{array}
  \quad n \geq 4 \quad D_3 \cong A_3 \quad \text{SO}_q, \quad \text{dim } q = 2n
  \]

- **E\(_6\):**
  \[
  \begin{array}{c}
  \alpha_1 \quad \alpha_2 \quad \alpha_3 \quad \alpha_4 \quad \alpha_5 \\
  \end{array}
  \]

- **E\(_7\):**
  \[
  \begin{array}{c}
  \alpha_1 \quad \alpha_2 \quad \alpha_3 \quad \alpha_4 \quad \alpha_5 \quad \alpha_6 \\
  \end{array}
  \]

- **E\(_8\):**
  \[
  \begin{array}{c}
  \alpha_1 \quad \alpha_2 \quad \alpha_3 \quad \alpha_4 \quad \alpha_5 \quad \alpha_6 \quad \alpha_7 \\
  \end{array}
  \]

- **F\(_4\):**
  \[
  \begin{array}{c}
  \alpha_1 \quad \alpha_2 \quad \alpha_3 \quad \alpha_4 \\
  \end{array}
  \]

- **G\(_2\):**
  \[
  \begin{array}{c}
  \alpha_1 \quad \alpha_2 \\
  \end{array}
  \]
Isogenies

An isogeny $\varphi$ is a $k$-morphism $H \to G$ of $k$-groups such that $\ker \varphi$ is finite and $\varphi$ is surjective over $\bar{k}$. (This implies that $H, G$ are of the same dimension.)

An isogeny $\varphi$ is central if $\ker \varphi \subset \text{center} H$.

The $k$-group $G$ and $G'$ are strictly isogenous if there exists a $k$-group $H$ and central isogenies $\varphi : H \to G$ and $\varphi' : H \to G'$.

A semisimple $k$-group $G$ is simply connected, if there is no proper central isogeny $G' \to G$ with a semisimple $k$-group $G'$. It is adjoint, if its center is trivial. It is known that for each semisimple $k$-group there exists a simply connected $k$-group $\hat{G}$, and an adjoint group $\bar{G}$. Hence that there are central isogenies $\hat{G} \to G \to \bar{G}$. The kernel of the composite (which is a central isogeny as well), is the center of $\hat{G}$ and a finite group, which only depends on the Dynkin diagram of $G$ ([24], §8).

Examples:

i) $\text{SL}_n, \text{PGL}_n$ are simply connected, resp. adjoint, the natural map $\text{SL}_n \to \text{PGL}_n$ is a central isogeny, and its kernel is cyclic of order $n$.

ii) Let $q$ be a nondegenerate quadratic form over a field $k$ of characteristic $\neq 2$. The homomorphisms $\text{Spin}_q \to \text{SO}_q \to \text{PSO}_q$ are central isogenies as well as their composite, $\text{Spin}_q$ is simply connected, $\text{PSO}_q$ is adjoint. If $\dim q$ is odd, one has $\text{SO}_q \cong \text{PSO}_q$, otherwise (i.e., if $\dim q$ is even), the kernel of $\text{SO}_q \to \text{PSO}_q$ is of order 2. Moreover

$\center \text{center } \text{Spin}_q \cong \begin{cases} Z_2 & \text{if } \dim q \text{ is odd} \\ Z_4 & \text{if } \dim q \equiv 2 \mod 4 \\ Z_2 \times Z_2 & \text{if } \dim q \equiv 0 \mod 4 \end{cases}$

For the definition of $\text{Spin}_q$ cf. [10], 7.2A, or any book on quadratic forms.

Main classification theorem: $k = \bar{k}$

The following is the main theorem for semisimple $k$-groups over algebraically closed fields $k$. It was proved by W. Killing (1888) for $K = C$, and for arbitrary algebraically closed fields by C. Chevalley (1958).

**Theorem 3.1** i) A semisimple $k$-group is characterized, up to strict isogeny, by its Dynkin diagram.
ii) A semisimple $k$-group is almost simple if and only if its Dynkin diagram is connected.

iii) Any semisimple $k$-group $G$ is isogeneous to the direct product of simple groups whose Dynkin diagrams are the connected components of the Dynkin diagram of $G$.

**Chevalley groups (arbitrary $k$):**

**Proposition 3.2** For field $k$ and any Dynkin diagram $\mathcal{D}$ there exists a semisimple $k$-group $G$ such that $\mathcal{D}$ is the Dynkin diagram of $G$.

**Remark:** A group $G$ like this exists even over $\mathbb{Z}$. This was proved by Chevalley, a proof can be found in [27].

**Definition** A Chevalley group over $k$ is a semisimple $k$-group with a split maximal $k$ torus.

**Structural theorem for Chevalley groups:**

Let $k$ be any field, and let $G$ be a Chevalley group over $k$ with maximal split torus $T$ and $\Sigma$ a set of roots for $G$ with respect to $T$.

**Theorem 3.3**  

i) For each $\alpha \in \Sigma$, there exists a $k$-isomorphism $u_\alpha : G \rightarrow U_\alpha$ onto a unique closed $k$-subgroup $U_\alpha \subset G$, such that $t u_\alpha(x) t^{-1} = u_\alpha(\alpha(t)x)$ for all $t \in T, x \in k$. Moreover, $G(k)$ is generated by $T(k)$ and all $U_\alpha(k)$.

ii) For every ordering of $\Sigma$, there is exactly one Borel group $B$ of $G$ with $T \subset B$ such that $\alpha > 0$ if and only if $U_\alpha \subset B$.

Moreover, $B = T \cdot \prod_{\alpha > 0} U_\alpha$ and $\text{rad}_B B = \prod_{\alpha > 0} U_\alpha$.

iii) The subgroup $\langle U_{-\alpha}, U_\alpha \rangle$ is isogeneous to $\text{SL}_2$ for every $\alpha \in \Sigma$.

iv) (Bruhat decomposition) Let $N = \text{Norm}_G(T)$, then $W = N/T$ is the Weyl group, we have a disjoint decomposition of $G(k)$ into double cosets: $G(k) = B(k) N(k) B(k) = B(k) W B(k) = \cup_{w \in W} B(k) W B(k)$. 
Parabolic subgroups

Let $G$ be a semisimple $k$-group with a split maximal $k$-torus (i.e., $G$ is a Chevalley group) with root system $\Sigma$, let $B$ be a Borel group containing $T$, and let $\Delta \subset \Sigma$ be the set of simple roots corresponding to $B$.

- There is a 1-1 correspondence of parabolic subgroups $P_\theta$ containing $B$ and the subsets $\theta \subset \Delta$, given by:
  $$\Theta \mapsto P_\theta = \langle T, U_{\alpha \in \Delta}, U_{-\alpha (\alpha \in \Theta)} \rangle.$$  
  In particular one has $B = P_\emptyset$ and $G = P_\Delta$.

- For $\Theta \subset \Delta$, let $W_\Theta = \langle s_\alpha \in W \mid \alpha \in \Theta \rangle$.
  There is a Bruhat decomposition into double cosets (disjoint, as usual):
  $$P_\Theta(k) = \bigcup_{w \in W_\Theta} B(k)wB(k).$$

The structure of $P_\Theta$ is as follows: It has a so-called Levi decomposition:

$$P_\Theta = L_\Theta \ltimes \text{rad}_u P_\Theta.$$  
$L_\Theta$ here is the Levi subgroup of $P_\Theta$. This is a reductive $k$-group, obtained as the centralizer of the $k$-torus $T_\Theta := \bigcap_{\alpha \in \Theta} (\text{Ker}\, \alpha)^0 \subset T$.

Hence

$$L_\Theta = Z_G(T_\Theta).$$

The unipotent radical is described by

$$\text{rad}_u P_\Theta = \langle U_\alpha \mid \alpha > 0, \, \alpha \notin \sum_{\gamma \in \Theta} \mathbb{R}\gamma \rangle,$$

i.e., it is generated by all $U_\alpha$ for which $\alpha > 0$ and $\alpha$ is not a linear combination of elements from $\Theta$. 
Remark:

The data \((G(k), B(k), N, S)\) with \(S = \{ s_\alpha \mid \alpha \in \Delta \}\) fulfill the axioms of a “BN pair” or a “Tits system” in the sense of [6], chap. IV, §2.

These axioms are the foundation for the setup of the so-called “buildings”, which give a geometrical description of the internal groups structure of Chevalley groups.

4 K-theoretic results related to Chevalley groups

Let \(G\) be a simply connected Chevalley group over \(k\), (i.e., having no proper algebraic central extension), let \(T\) be a maximal split torus and \(\Sigma\) the set of roots of \(G\) for \(T\).

For \(\alpha \in \Sigma\), recall the embeddings \(u_\alpha : G_a \to U_\alpha \subset G\) from the last section, and define:

\[
\begin{align*}
w_\alpha(x) &= u_\alpha(x)u_{-\alpha}(-x^{-1})u_\alpha(x) \quad (x \in k, x \neq 0) \\
h_\alpha(x) &= w_\alpha(x)w_\alpha(-1) \quad (x \in k, x \neq 0)
\end{align*}
\]

The Steinberg relations for \(G\):

For every \(x, y \in K\) and \(\alpha, \beta \in \Sigma\):

\[
\begin{align*}
(A) \quad u_\alpha(x + y) &= u_\alpha(x)u_\alpha(y) \\
(B) \quad [u_\alpha(x), u_\beta(y)] &= \prod_{i,j > 0 \atop i\alpha + j\beta \in \Sigma} u_{i\alpha + j\beta}(c_{\alpha\beta,ij} x^i y^j) \\
\end{align*}
\]

Here the product is taken in some lexicographical order, with certain coefficients \(c_{\alpha\beta,ij} \in \mathbb{Z}\), called structure constants, independent of \(x, y\) and only dependent on the Dynkin diagram of \(G\).

\[
\begin{align*}
(B') \quad w_\alpha(t)u_\alpha(x)w_\alpha(t)^{-1} &= u_{-\alpha}(-t^{-2}x), \quad \text{for } t \in k^*, x \in k. \\
(C) \quad h_\alpha(xy) &= h_\alpha(x)h_\alpha(y)
\end{align*}
\]

Theorem 4.1 (Steinberg, [25], Thms. 3.1, 3.2 ff., Thm. 4.1 ff. Theorem 1.1 in section 1 was just the special case \(G = SL_n\).)

Given \(\Sigma\), there exists a set of structure constants \(c_{\alpha\beta,ij} \in \mathbb{Z}\) for \(\alpha, \beta, i\alpha + j\beta \in \Sigma, (i, j \geq 1)\), such that the following holds.
i) Let $\hat{G}$ denote the simply connected covering of $G$. A presentation of $\hat{G}(k)$ is given by

(A), (B), (C) if rank $G \geq 2$, and

(A), (B'), (C) if rank $G = 1$.

ii) Denote by $\tilde{G}$ the group given by the presentation

(A), (B) if rank $G \geq 2$, and

(A), (B') if rank $G = 1$,

Then the canonical map $\pi : \tilde{G} \rightarrow \hat{G}(k)$ is central, and $\tilde{G}$ is perfect, i.e., $\tilde{G} = [\tilde{G}, \tilde{G}]$.

If, moreover, $|k| > 4$ for rank $G > 1$, and $|k| \neq 4, 9$ for rank $G = 1$, then $\tilde{G}$ is the universal central extension of $\hat{G}(k)$.

(Note: $\tilde{G}$ is not an algebraic group!)

Remarks:

- Again, $\tilde{G}$, as universal extension of $\hat{G}(k)$, is unique up to isomorphism. For given $\Sigma$, the group $St_\Sigma(k) = \tilde{G}$ is called the Steinberg group for the Chevalley groups defined by $\Sigma$ or just the Steinberg group of $\Sigma$.

- If $k$ is finite, then $\tilde{G}$ and $\hat{G}(k)$ are equal.

- The relation (B') is a consequence of the relations (A), (B) in case rank $\Sigma) > 1$.

- There are various possible choices for the sets of “structure constants”, the interdependence of the coefficients for a given Chevalley group is delicate, cf. [24], 9.2 for a discussion.

- The roots occurring on the right of (B) can be read off the two dimensional root systems, since $\{\alpha, \beta\}$ generate a sub-root system of rank 2. E.g., for $G = G_2$, one may have:

$$[u_\alpha(x), u_\beta(y)] = u_{\alpha+\beta}(x y) u_{2\alpha+\beta}(-x^2 y) u_{3\alpha+\beta}(-x^3 y) u_{3\alpha+2\beta}(x^3 y^2)$$

and this is the longest product which might occur (cf. [27], p. 151 – please note that long and short roots are differently named there).

For groups of type different from $G_2$, at most two factors do occur on the right of (B).
• Each relation involves only generators of some almost simple rank 2 subgroups (generated by $u_\alpha(x), u_\beta(y)$ involved, hence the theorem implies that $\hat{G}(k)$ is an amalgamated product of its almost simple rank 2 subgroups.

**Theorem 4.2** (Matsumoto, cf. [12], Prop. 5.5 ff., Thm. 5.10, Cor. 5.11, see also Moore[16]):

For $\alpha \in \Sigma$, define $c_\alpha(x, y) := h_\alpha(x)h_\alpha(y)h_\alpha(xy)^{-1} \in \hat{G}$.

Then, for each long root $\alpha \in \Sigma$, the values $c_\alpha(x, y), x, y \in k^*$ generate the kernel of $\pi : \hat{G} \to \hat{G}(k)$.

They fulfill the following set of relations (setting $c(x, y) := c_\alpha(x, y)$), which gives a presentation of kernel $\pi$:

**rank $G = 1$ or $G$ symplectic:** (cf. [12], Prop. 5.5)
(S1) $c(x, y) c(xy, z) = c(x, yz) c(y, z)$
(S2) $c(1, 1) = 1, c(x, y) = c(x^{-1}, y^{-1})$
(S3) $c(x, y) = c(x, (1 - x)y)$ for $x \neq 1$

**rank $\geq 2$ and $G$ not symplectic:** (cf. [12], Lemme 5.6)
(S°1) $c(x, yz) = c(x, y) c(x, z)$
(S°2) $c(xy, z) = c(x, z) c(y, z)$
(S°3) $c(x, 1 - x) = 1$ for $x \neq 1$

Define $c^\wedge(x, y) := c(x, y^2)$. Then $c^\wedge(x, y)$ fulfills the relations (S°1), (S°2), (S°3).

**Remarks:**

Hence we have two groups, the “usual” $K_2(k)$, occurring as the kernel of $\pi$ for non-symplectic groups (excluding $\text{SL}_2$) and the “symplectic: $K_2^\text{sym}$, occurring as the kernel of $\pi$ for the symplectic groups as well as for $\text{SL}_2$:

$K_2^\text{sym}(k)$ defined by generators and relations as in (S1), (S2), (S3)
$K_2(k)$ defined by generators and relations (S°1), (S°2), (S°3)

From the theorem, we also obtain two homomorphisms

$K_2^\text{sym}(k) \to K_2(k)$ $c(x, y) \mapsto c(x, y)$,
$K_2(k) \to K_2^\text{sym}(k)$ $c(x, y) \mapsto c^\wedge(x, y) = c(x, y^2)$. 
These maps are interrelated in a surprising way with the Witt ring of the underlying field $K$ as described by Suslin ([28], §6 (p. 26)).

The Witt ring $W(k)$ of nondegenerate symmetric bilinear forms over $k$ contains the maximal ideal $I(k)$ of even dimensional forms as well as its powers $I^r(k), r = 1, 2, \ldots$

It is well known that $I^r(k)$ is generated by so-called Pfister forms $\langle \langle a_1, \ldots, a_r \rangle \rangle = \langle 1, a_1 \rangle \otimes \cdots \otimes \langle 1, a_r \rangle$.

Suslin observed two things:

i) There is a natural homomorphism $\varphi : K_2^{\text{sym}} \rightarrow I^2(k), \ c(x, y) \mapsto \langle \langle x, y \rangle \rangle$, and kernel $\varphi$ is generated by $(x, y) = c(x, y^2)$. This gives rise to an exact sequence

\[ 1 \rightarrow K_2(k) / \{ c(x, -1) \mid x \in k^* \} \rightarrow K_2^{\text{sym}}(k) \xrightarrow{\varphi} I^2(k) \rightarrow 1. \]

ii) There is an isomorphism $\psi$ from the kernel of $K_2^{\text{sym}}(k) \rightarrow K_2(k)$ onto $I^3(k)$, sending each element $c(x, y) c(x, z) c(x, yz)^{-1}$ to the Pfister form $\langle \langle x, y, z \rangle \rangle$. This yields an exact sequence

\[ 1 \rightarrow I^3(k) \xrightarrow{\psi} K_2^{\text{sym}}(k) \rightarrow K_2(k) \rightarrow 1. \]

Combining this for char $k \neq 2$, one gets the following diagram with exact rows and columns, where $\text{Br}_2(k)$ denotes the 2-torsion part of the Brauer group of $k$:

The exactness of the third vertical sequence is just the norm residue theorem by Merkurjev and Suslin (cf. [14]).
This diagram can be found as well in [10], 6.5.13.

Since $K_2(2, k) = K_2^{\text{sym}}(k)$, we find, as a corollary, the following exact sequence:

$$1 \longrightarrow I^3(k) \longrightarrow K_2(2, k) \longrightarrow K_2(2, k) \longrightarrow 1$$

This has been generalized: In [17], it is shown that for the Laurent polynomial ring $k[\xi, \xi^{-1}]$, there are the following exact sequences:

$$1 \longrightarrow I^3(k) \oplus I^2(k) \longrightarrow K_2^{\text{sym}}(k[\xi, \xi^{-1}]) \longrightarrow K_2(k[\xi, \xi^{-1}]) \longrightarrow 1$$

Here $N(k)$ denotes the subgroup of $K_2(k)$ generated by $c(x, -1)$ with $x \in k^*$. These sequences give rise to a similar commutative diagram as above, cf. [17].
5 Structure and classification of almost simple algebraic groups

Let \( k \) be a field, \( k_s \) a separable closure of \( k \) and \( \Gamma = \text{Gal}(k_s/k) \) and \( G \) a semisimple \( k \)-group.

The anisotropic kernel of \( G \):

Denote by \( S \) a maximal \( k \)-split torus of \( G \), and assume that \( T \) is a maximal torus of \( G \) defined over \( k \) and containing \( S \). This can be achieved by taking \( T \) as a maximal \( k \)-torus in the centralizer of \( S \) in \( G \), which is a connected reductive \( k \)-subgroup of \( G \) by [24], 15.3.2.\(^3\)

A proof of the existence of \( T \) can be found in [24], 13.3.6ff. This important theorem had first been proved by Chevalley for characteristic 0, and later in general by Grothendieck [7] Exp XIV. Since every \( k \)-torus is an almost direct product of a unique anisotropic and a unique split \( k \)-subtorus (cf, [24] 13.2.4), we obtain \( S \) as the split part of \( T \).

Since all maximal split \( k \)-tori of \( G \) are conjugate over \( k \) (cf. [24], 15.2.6), they are isomorphic over \( k \), and hence the dimension of \( S \) is an invariant of \( G \), called the \( k \)-rank of \( G \) and denoted by \( \text{rank}_k G \).

\( T \) can be split over a finite separable extension, and since any semisimple group with a split maximal torus is a Chevalley group, this is true for \( G \times_k k_s \).

Remark: \( T \) and \( S \) are usually different, as seen by the following example:

Take \( G = \text{SL}_{r+1}(D) \), where \( D/k \) is a central \( k \)-division algebra of degree \( d > 1 \).

By a theorem of Wedderburn, \( G \times_k k_s(k_s) \cong \text{SL}_{r+1}(M_d(k_s)) \cong \text{SL}_{d(r+1)}(k_s) \)

\(^3\)It should be mentioned here that \( \text{SL}_{r+1}(D) \), as an algebraic group, is defined to be the kernel of the “reduced norm” \( \text{RN} : M_{r+1}(D) \to k \), defined as follows. Let \( A \) be any finite dimensional central simple \( k \)-algebra. Then, by Wedderburn’s theorem, \( A \otimes_k k \cong M_m(k) \) for some \( m \), hence \( \text{dim}_k A = m^2 \). The characteristic polynomial \( \chi_{a \otimes 1} \) of the matrix \( a \otimes 1 \) for any \( a \in A \) has coefficients in \( k \) and is independent of the embedding of \( A \) in \( M_m(k) \) (cf. [7], Algèbre...):

\[
\chi_{a \otimes 1}(X) = X^m - s_1(a)X^{m-1} + s_2(a)X^{m-2} + \cdots + (-1)^ms_m(a).
\]

Clearly, \( s_1(a) \), \( s_m(a) \) are trace and determinant of \( a \otimes 1 \), they are called the reduced trace and the reduced norm of \( a \), and are obtained as polynomials with coefficients in \( k \): \( \text{RS}(a) = s_1(a), \text{RN}(a) = s_m(a) \), hence \( \text{RS} : A \to k \) is \( k \)-linear and \( \text{RN} : A \to k \) is multiplicative.

In our example above, \( A = M_{r+1}(D) \).
A maximal split torus \( S \subset \text{SL}_{r+1}(D) \) is given by the diagonal matrices with entries in \( k \) and of determinant 1, hence \( S \cong G_m^r \). A maximal torus in \( \text{SL}_{d(r+1)}(k_s) \) also consists of the diagonal matrices of determinant 1 and hence has dimension \((r + 1)d - 1\).

Hence we have \( \text{rank}_k \text{SL}_{r+1}(D) = r \), and \( \text{rank} \text{SL}_{r+1}(D) = (r + 1)d - 1 \).

We see in this case that \( \text{rank}_k \text{SL}_{r+1}(D) = \text{rank} \text{SL}_{r+1}(D) \) if and only if \( d = 1 \), i.e., if and only if \( D = k \).

The other extreme case is \( \text{rank}_k \text{SL}_{r+1}(D) = 0 \), which means that \( r = 0 \), hence our group is \( \text{SL}_1(D) \), the group of elements in \( D \) which are of reduced norm 1.

**Definition**

The group \( G \) is called *isotropic* if it contains a non trivial \( k \)-split torus (i.e., if \( \text{rank}_k G > 0 \)), and *anisotropic* otherwise.

**Examples:**

i) Let \( D/k \) be as above and \( G = \text{SL}_{r+1}(D) \). As we have seen, this is isotropic if and only if \( r > 0 \).

ii) Let \( q \) be a regular quadratic form over \( k \). Then we have a Witt decomposition

\[
q = q_{an} \perp \mathbb{H}^r
\]

into the “anisotropic kernel” \( q_{an} \) of \( q \) and a direct sum of \( r \geq 0 \) hyperbolic planes. The anisotropic kernel \( q_{an} \) is uniquely determined by \( q \) up to isometry. \( r \) is called the *Witt index* of \( q \) and is of course also uniquely determined by \( q \).

We have \( \text{SO}(\mathbb{H}) \cong G_m^m \), hence \( \text{SO}_q \) admits the embedding of a split \( k \)-torus \( S \cong G_m^r \) (one for each summand \( \mathbb{H} \)), and in fact this is maximal: \( \text{rank}_k \text{SO}_q = r \).

Over \( k_s \) the number of \( \mathbb{H} \)-summands in the Witt decomposition attains the maximal possible value \( \lfloor \dim q/2 \rfloor \).

Hence we have \( \text{rank} \text{SO}_q = \lfloor \dim q/2 \rfloor \), and \( \text{SO}_q \) is anisotropic if and only if \( q \) is anisotropic as a quadratic form.
Arbitrary semisimple \( k \)-groups behave similarly as quadratic forms do under the Witt decomposition as seen in the preceding example.

In order to understand the following construction it is helpful to think of the example \( \text{SO}_q \) as being represented using the Witt decomposition.

We introduce the following notation for certain \( k \)-subgroups of \( G \):

\[
\begin{align*}
Z(S) & \quad \text{the centralizer of } S \text{ in } G \quad (= \text{reductive}) \\
\text{DZ}(S) & = [Z(S), Z(S)] \quad \text{its derived group} \quad (= \text{semisimple}) \\
Z_a & \quad \text{max. anisotropic subtorus of center}(Z(S))
\end{align*}
\]

If we “visualize” these groups for \( \text{SO}_q \) by matrices with respect to a basis aligned along a Witt decomposition for \( q \) as above, \( q = q_{an} \perp \mathbb{H}^r \), the matrices for \( Z(S) \) look as follows:

\[
\begin{pmatrix}
\text{DZ}(S) & 0 & \cdots & \cdots & \cdots & 0 \\
0 & s_1 & 0 & \cdots & \cdots & \cdots \\
\vdots & 0 & s_1^{-1} & \ddots & \cdots & \cdots \\
\vdots & \ddots & \ddots & \ddots & \cdots & \cdots \\
\vdots & \cdots & \cdots & \cdots & s_r & 0 \\
0 & \cdots & \cdots & \cdots & 0 & s_r^{-1}
\end{pmatrix}
\]

\( \text{DZ}(S) \) is a \( \text{dim } q_{an} \times \text{dim } q_{an} \)-matrix, and each \( s_i, s_i^{-1} \) pair is a torus component and belongs to a copy of \( \mathbb{H} \). The torus \( Z_a \) is a maximal \( k \)-torus in \( \text{DZ}(S) \), hence \( T = Z_a S \) as an almost direct product.

**Definition**

i) The group \( \text{DZ}(S) \) is called a **semisimple anisotropic kernel of** \( G \),

ii) the group \( \text{DZ}(S) \cdot Z_a \) is called a **reductive anisotropic kernel of** \( G \).

**Proposition 5.1**

i) The semisimple anisotropic kernels of \( G \) are precisely the subgroups occurring as derived group of the Levi-\( k \)-subgroups (=semisimple parts) of the **minimal parabolic** \( k \)-subgroups. Any two such are conjugate under \( G(k) \).
ii) The anisotropic kernels of $G$ are anisotropic $k$-groups.

iii) The group $G$ is quasi-split (i.e., has a $k$-Borel subgroup) if and only if its semisimple anisotropic kernel is trivial.

The Tits index of a semisimple group $G$:

Let $\Delta$ be a system of simple roots of $G \times_k k_s$ with respect to $T$ (and some ordering) and define $\Delta_0 = \{ \alpha \in \Delta \text{ such that } \alpha|_S = 0 \}$

Then $\Delta_0$ is the set of simple roots of $DZ(S)$ with respect to $T \cap DZ(S)$. The group $\Gamma = \text{Gal}(k_s/k)$ acts on $\Delta$ as follows: To each $\alpha \in \Delta$, we associate the maximal proper parabolic subgroup $P_{\Delta_0 \setminus \alpha}$ (each represents one of these conjugacy classes).

The group $\Gamma$ operates on the set of conjugacy classes of parabolic subgroups, and thereby on $\Delta$:

$$(\gamma, \alpha) \mapsto \gamma \ast \alpha \quad (\gamma \in \Delta)$$

This operation is called the $\ast$-operation or star-operation.

Beware! This is not(!) the same as $\gamma \alpha$, as this root usually is not in $\Delta$. Namely, $\gamma$ induces a switch of the ordering of $\Delta$ (which is defined by its underlying Weyl chamber), but then there is a unique $w \in W$ with $w(\gamma \Delta) = \Delta$, as $W$ operates simply transitively on the Weyl chambers. Hence $\gamma \ast \alpha = w \gamma \alpha$.

Definition (Tits index):

- The group $G$ is said to be of inner type if the $\ast$-operation is trivial.
- The group $G$ is said to be of outer type if not.
- The Tits index of $G$ is given by $(\Delta, \Delta_0)$ together with $\ast$-operation (leaving $\Delta_0$ invariant).

The subset $\Delta_0 = \{ \alpha \in \Delta \text{ such that } \alpha|_S = 0 \}$ is called the system of distinguished roots of $G$.

Remark: Only the following Dynkin diagrams allow non-trivial automorphisms and therefore are candidates for the $\ast$-operation:
Therefore, only groups with these Dynkin diagrams may allow outer types, all the others are a priori of inner type.

**Theorem 5.2**  

i) (Pre-classification Witt-type theorem, cf. [24], 16.4.2)  
The group $G$ is uniquely determined by its Tits index and by its anisotropic kernel, if the semisimple anisotropic kernel is nontrivial (i.e., if $G$ is not quasisplit).

Otherwise (in the split or quasi-split case) $G$ is determined by its Tits index and by its anisotropic kernel up to strict isogeny.

ii) (Pre-structural theorem, this is a special case of [24], 16.1.3) Let $P$ be a minimal parabolic subgroups of $G$, then there is a Bruhat decomposition  

$$G(k) = \bigcup_{w \in \Delta \setminus \Delta_0} P(k)WP(k)$$

into pairwise disjoint cosets mod $P$.

**Remarks:**

ii) holds in fact for arbitrary $k$-parabolic subgroups, as [24] 16.1.3 says. However, the case of a minimal parabolic gives most of the structural information for $G(k)$ and “burns everything down” to anisotropic groups, which are structurally widely unknown.
All the results above don’t say anything about anisotropic groups or about anisotropic kernels of $G$, since that kernel is hidden in the Levi-group of $P$.

**Notation for the Tits index of $G$:**

The notation for the Dynkin type is enriched as follows: The symbol

$$gX_{n,r}^t$$

is used in order to describe a group $G$ over $k$ of Dynkin type $X$, where $n = \text{rank } G$, $r = \text{rank}_k G$, $g$ is the order of the outer automorphism group employed by the $\ast$-operation (left out in case this is 1, i.e., if $G$ is of inner type), and $t$ is either (for groups of type A, C, D) the index of a central $k$-division algebra involved in the definition of $G$, or the dimension of its anisotropic kernel (for the “exceptional” groups defined by the exceptional root systems as explained in section 3). To distinguish both cases, if $t$ denotes an index of a division algebra, it is put between parentheses.

In the Dynkin diagram, roots which are rational over $k$ are marked as bullets, the others, which occur over $k_s$, are marked as circles.

**Examples:**

- **Type: $1A_n^{(d)}$:** simply connected group $\text{SL}_{r+1}(D)$, $D/k$ a central division algebra of degree $d$. Conditions: $d(r + 1) = n + 1$.
  
  Tits-Dynkin diagram:

  $$
  \begin{array}{c}
  \alpha_1 \cdots \alpha_d \alpha_{d+1} \cdots \alpha_n \\
  \frac{d-1}{d-1} \\
  \end{array}
  $$

- **Type: $B_{n,r}$:** Special orthogonal groups of regular quadratic forms with Witt index $r$ and dimension $2n + 1$.
  
  Tits-Dynkin diagram:

  $$
  \begin{array}{c}
  \alpha_1 \alpha_2 \cdots \alpha_{r+1} \alpha_{n-1} \alpha_n \\
  \end{array}
  $$
• Type: $C_{n,r}^d$: Special unitary group $SU_{2n/d}(D, h)$, where $D$ is a division algebra of degree $d$ over $k$, and $H$ is a non-degenerate antihermitian sesquilinear form of index $r$ relative to an involution of the first kind of $D$. For $d = 1$ this group is just $Sp_{2n}(k)$.

Tits-Dynkin diagram:

![Tits-Dynkin diagram](image)

• Type: $1D_{n,r}^d$: chark $\neq 2$: Special unitary group $SU_{2n/d}(D, h)$, where $D$ is a division algebra of degree 2 over $k$, and $H$ is a non-degenerate hermitian form of discriminant 1 and index $r$ relative to an involution of the first kind of $D$. In case $d = 1$ this becomes $SO_q(k)$ for a regular quadratic form of Witt index $r$, dimension $2n$ and trivial discriminant.

Tits-Dynkin diagram:

![Tits-Dynkin diagram](image)

6 Further K-theoretic results for simple algebraic groups

Most $K$-theoretic results deal with so-called “classical groups”, these are the groups $SL_n$ over a skew field, and unitary groups for various (skew)-hermitian forms. These groups are not necessarily algebraic – for example, the group $SL_n(D)$ as defined by the Dieudonné determinant, is in general not algebraic, when $D$ is not of finite dimension over its center. A very good accounting of these results is given in the book by Hahn and O’Meara (“The classical groups and $K$-theory”, [10]).

The results are also mostly under the assumption that the groups under consideration have “many” transvections. Insomuch the groups are algebraic, this amounts to assuming that they are split (Chevalley groups) or at least quasi-split (i.e., having a Borel group over the field of definition).
The methods are variations of classical $K$-theory methods as well as those used by Steinberg-Matsumoto, but also, the study of generalized Witt groups plays a big role.

However, a few results concern groups with a non-trivial anisotropic kernel, which we will discuss here.

**On $K_2$ of skew fields:**

For a skew field $D$, there is the “Dieudonné Determinant”

\[
\det : \text{GL}_n(D) \to D^*/[D^*, D^*]
\]

which has essentially the same properties as the determinants for fields (Np. [8], or for an alternative approach, [9], Teil 1, 2. Vortrag). Its definition specializes to the ordinary determinant if $D$ is commutative. Its kernel $E_n(D)$ is generated by the elementary matrices $u_{ij}(x) = 1 + xe_{ij}$, $i \neq j$ and $x \in D$.

Again we have for $n \geq 3$ (we omit the technically more involved case $n = 2$):

\begin{enumerate}
\item[(A)] $u_{ij}(x + y) = u_{ij}(x)u_{ij}(y)$
\item[(B)] $[u_{ij}(x), u_{kl}(y)] = \begin{cases}
  u_{kl}(xy) & \text{if } i \neq l, j = k, \\
  u_{jk}(-yx) & \text{if } i = l, j \neq k, \\
  1 & \text{otherwise, provided } (i, j) \neq (j, i)
\end{cases}$
\item[(C)] $h_{ij}(xy) = h_{ij}(x)h_{ij}(y)$
\end{enumerate}

Please observe here the order of the factors $x$ and $y$ in the right-hand side of (B).

We have the standard definitions:

\begin{align*}
w_{ij}(x) &= u_{ij}(x)u_{ij}(-x^{-1})u_{ij}(x) \quad (x \in k, x \neq 0) \\
h_{ij}(x) &= w_{ij}(x)w_{ij}(-1) \quad (x \in k, x \neq 0)
\end{align*}

By Milnor ([15], 5.10), the group $\text{St}_n(D)$ presented by (A), (B) is a universal central extension of the perfect group $E_n(D)$, again its kernel is denoted by $K_2(n, D)$. 
Linear Algebraic Groups and $K$-theory

(In [12], the universality of the central extension is only proved for $n \geq 5$, for $n \geq 3$, compare [19], Kor. 1 and “Bemerkung”, p. 101.)

One also has a Bruhat double coset decomposition $E_n(D) = UMU$, here $M$ denotes the monomial matrices and $U$ the upper triangular matrices.

Let $\pi : St_n(D) \to E_n(D)$ be the canonical map, let us denote the generators of $St_n(D)$ by $\tilde{u}_{ij}(x), \tilde{w}_{ij}(x), and \tilde{h}_{ij}(x)$. Now the elements

$$c_{ij}(xy) = \tilde{h}_{ij}(xy)\tilde{h}_{ij}(x)^{-1}\tilde{h}_{ij}(y)^{-1} \in St_n(D)$$

are not any more in kernel $\pi$, as they map to the diagonal matrix

$$\begin{pmatrix}
1 & & & \\
& \ddots & & \\
& & 1 & \\
& & & 1 \end{pmatrix}$$

However, for $x_\nu, y_\nu \in D^*$ such that $\prod_\nu [x_\nu, y_\nu] = 1$, one has obviously $\prod_\nu c_{ij}(x_\nu, y_\nu) \in Ker \pi$, and all elements of $\ker \pi$ are of this type. It can be shown that these elements are independent of the choice of $(i, j)$, and one has the following replacement for Matsumoto’s theorem ([19]):

**Theorem 6.1** Let $U_D$ denote the group generated by $c(x, y)$, $x, y \in D^*$, subject to the following relations:

(U0) $c(x, 1-x) = 1, x \neq 0, 1$

(U1) $c(xy, z) = c(x, y) c(z)$

(U2) $c(x, yz) = c(x, y) c(yx, yz)$

(Here the abbreviation $xy := xyx^{-1}$ is used.) Then the map

$$U_D \to [D^*, D^*], \quad c(x, y) \mapsto [x, y]$$

defines a central extension of $[D^*, D^*]$.

Moreover, $U_D \to St_n(D)$ injects via

$$c(x, y) \mapsto c_{12}(x, y) = \tilde{h}_{12}(xy)\tilde{h}_{12}(x)^{-1}\tilde{h}_{12}(y)^{-1}$$
This implies that \( K_2(n, D) = K_2(D) \) for \( n \geq 3 \). Hence one has an exact sequence

\[
0 \rightarrow K_2(D) \rightarrow U_D \rightarrow [D^*, D^*] \rightarrow 0
\]

**Remarks:**

- Obviously, this gives Matsumoto’s theorem for \( D \) commutative and in general relates \( K_2(D) \) to a central extension of \([D^*, D^*]\).

- The relations \( U_1, U_2 \) together with the relations \( c(x, x) = 1 \) give a generating set for all formal commutator relations of an arbitrary group \( H \) and \( x, y \in H \).

  Applying the Hochschild-Serre spectral sequence to the central extension above we obtain the exact sequence:

\[
H_2(U_D) \rightarrow H_2([D^*, D^*]) \rightarrow K_2(D) \rightarrow H_1(U_D) \rightarrow H_1([D^*, D^*]) \rightarrow 1
\]

In general, \( E_n(D) \) is not an algebraic group; the Dieudonné determinant is not a polynomial function.

However, in certain cases this becomes true if \( D \) is a finite central \( k \)-division algebra: then both, \( D \) and \( M_n(D) \) are central simple \( k \)-algebras of finite dimension over \( k \). The Dieudonné determinant factors through to the reduced norm (see the previous section for the definition of the reduced norm). As this is a polynomial, \( E_n(D) \subset SL_n(D) \) in general, and we will below discuss some conditions which guarantee equality.

The exact sequence above about \( K_2(D) \) in this case should be understood as a statement which relates the central extensions of \( G = SL_{r+1}(D) \) to those of the anisotropic kernel of \( G \).

Therefore we will investigate this group in more detail here:

Let \( D/k \) be a finite central algebra of index \( d \), then \( \dim_k D = d^2 \). To understand the structure of \( SL_{r+1}(D) \) (up to its anisotropic kernel), we consider the subgroup of upper triangular matrices which in this case is a minimal parabolic subgroup:

\[
P := \left\{ \begin{pmatrix} * & * & * \\ \cdots & * \\ 0 & \cdots & * \end{pmatrix} \in SL_{r+1}(D) \right\}
\]
Its Levi decomposition looks as follows:

\[
P = L \rtimes R_n(P) = \left\{ \begin{pmatrix} * & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & * \end{pmatrix} \right\} \rtimes \left\{ \begin{pmatrix} 1 & * & * \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 1 \end{pmatrix} \right\}
\]

Each (*) in the Levi-group \( L \) is a copy of \( D^* = \text{GL}_1(D) \) with a central torus \( \mathbb{G}_m \) (the center of \( D^* = k^* \), there are \( r + 1 \) copies, but with reduced norm 1, hence the central torus in \( L \) has dimension \( r \):

\[
S = \left\{ \begin{pmatrix} a_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & a_{r+1} \end{pmatrix} | a_i \in k^*, \prod_{i=1}^{r+1} a_i = 1 \right\}
\]

This is a maximal \( k \)-split torus of \( G = \text{SL}_{r+1}(D) \), and obviously \( L \) is its centralizer.

The semi-simple anisotropic kernel consists of the diagonal matrices with \( r + 1 \) copies of \( \text{SL}_1(D) \).

The group \( \text{SL}_{r+1}(D) \) is of inner type, because all roots are kept invariant under \( \text{Gal}(k_s/k) \), hence its type is \( 1A_{n,r} \).

Since \( \text{SL}_{r+1}(D) \times_k k_{\text{sep}} \cong \text{SL}_{r+1}(M_d(k_{\text{sep}})) \cong \text{SL}_{(r+1)d}(k_{\text{sep}}) \), we have \( n = \text{rank } \text{SL}_n(D) = (r + 1)d - 1 \).

The Tits-Dynkin diagram for this group looks like this:

\[
\begin{array}{cccccc}
\alpha_1 & \cdots & \alpha_d & \cdots & \alpha_{rd} & \cdots & \alpha_n \\
\end{array}
\]

The distinguished roots are: \( \Delta_0 = \{ \alpha_d, \alpha_{2d}, \ldots, \alpha_{rd} \} \), and one has \( n+1 = (r + 1)d \),

**Consequences for the determination of \( K_2(D) \):**

There are results only for special classes of fields \( k \):

**Theorem 6.2** (Alperin/Dennis, cf. [1]) Let \( H \) the skew field of Hamilton’s quaternions over \( \mathbb{R} \). Then the natural embedding \( \mathbb{R} \rightarrow H \) induces an isomorphism \( K_2(\mathbb{R})/\mathbb{Z}(-1,-1) \rightarrow K_2(H) \).
For division algebras $D$ over local or global fields $k$, several results have been achieved by Rehmann and Stuhler in [20]. The methods and results there are as follows:

Define $N_{D/k} := \text{Image}(RN : D^* \longrightarrow k^*)$, then there exists (under the assumption that $\text{kernel}(RN) = [D^*, D^*]$, which is true for local and global fields – see the next section about this assumption) a bimultiplicative map $\psi_0 : N_{D/k} \times k^* \longrightarrow K_2(D)$, defined by $\psi_0(RN(x), z) = c(x, z)$ for $x \in D^*, z \in k^*$. (The right-hand side indeed only depends on $z$ and on $RN(x)$, not on the choice of $x$ in the pre-image of $RN(x)$.) Under certain conditions on $D$, which always hold for local and global fields, $\psi_0$ turns out to be a symbol, i.e., $\psi_0(\alpha, 1 - \alpha) = 0$ for any $\alpha \in N_{D/k}$.

We define $Y(D/k) := N_{D/k} \otimes k^*/\langle c(a, 1 - \alpha) \mid \alpha \in N_{D/k} \rangle$. Then we obtain a homomorphism $\psi : Y(D/k) \longrightarrow K_2(D)$.

Of course there is also a natural map $\iota : Y(D/k) \longrightarrow K_2(k) \longrightarrow K_2(D)$, given by $x \otimes y \mapsto c(x, y) \in K_2(D)$. It turns out that

$$\psi = \iota^d \text{ for } d = \text{degree } D. \quad (*)$$

Now if $RN$ is an epimorphism (which is true for non-Archimedean local fields or for global fields with no real places), then $Y(D/k) = K_2(k)$.

By another result of Alperin-Dennis (11) it can be shown that for quaternion algebras, $\psi$ is always surjective.

If $k$ is a global function field, then it is shown in [20] that:

$$K_2(D) = K_2(k) \times \text{finite group},$$

and if $D$ in addition is a quaternion division algebra (i.e., $\dim_k D = 4$), then:

$$K_2(k) \cong K_2(D)$$

But it is important to realize that this isomorphism is not induced by the natural embedding $k \longrightarrow D$ – it is something like $1/d$ times this map, by the fact $(*)$ above.

There are similar results of this type for number fields in [20].

The map $\psi$ seems to something like the inverse of the “reduced $K_2$-norm” for division algebras of square-free degree as constructed by Merkurjev and Suslin:
Theorem 6.3 (Merkurjev, Suslin, cf. [14]): If $D$ is of square-free degree, then there exists a unique homomorphism $\text{RN}_{K_2} : K_2(D) \rightarrow K_2(k)$, such that for every splitting field $L/k$ of $D$ the transfer map $N_{L/k} : K_2(L) \rightarrow K_2(k)$ factorizes through $\text{RN}_{K_2}$, such that the following diagram commutes:

\[
\begin{array}{c}
K_2(L) \xrightarrow{\iota} K_2(D) \\
\downarrow N_{L/F} & \downarrow \text{RN}_{K_2} \\
K_2(k) &
\end{array}
\]

Here $\iota$ denotes the map induced by some embedding of $L$ into some $M_1(D)$.

From this, the following is deduced:

Theorem 6.4 (Merkurjev, Suslin, cf. [14]) If $D$ is a division algebra of square-free degree over a local or global field, then the sequence

\[
0 \rightarrow K_2(D) \xrightarrow{\text{RN}_{K_2}} K_2(F) \rightarrow \bigoplus_v \mathbb{Z}/2\mathbb{Z} \rightarrow 0
\]

is exact, where the sum is taken over all real places of $k$ for which $D_v$ is non-trivial.

This generalizes some of the results from [20] to a certain extent, but only under the assumption of a square-free index. It is expected that, at least for results on local or global fields, this restriction should not be necessary.

Results and open questions on $SK_1(D)$:

We have $\text{SL}_1(D) = \text{kernel}(\text{RN} : D^* \rightarrow k^*)$, hence $[D^*, D^*]$ is contained in $\text{SL}_1(D)$.
The abelian quotient group $\text{SL}_1(D)/[D^*,D^*]$ is denoted by $\text{SK}_1(D)^4$.

The question in general is still open: What is $\text{SK}_1(D)$?

Wang (1950) proved (29):

**Theorem 6.5** For any finite dimensional central $k$-division algebra $D$ of degree $d$ one has $\text{SK}_1(D) = 1$, if

i) either $k$ is arbitrary and $d$ is square free,

ii) or $k$ is local or global and $d$ is arbitrary.

It was a long standing open question whether $\text{SK}_1(D)$ is always trivial, in fact this was stated as the “Artin-Tannaka”-conjecture.

But around 1975, V. P. Platonov (in [18] and several subsequent articles) gave first examples of a finite central algebra $D/k$ and $\text{SK}_1(D) \neq 1$, which were constructed over a twofold valuated field $k$.

The theory was further developed by P. K. J. Draxl, who proved that, for any finite abelian group $A$, there exists $D$ such that $\text{SK}_1(D) = A$ (cf. [9]).

A. Suslin conjectured in 1990 that only in the case of square free degree, $\text{SK}_1(D)$ should “generically vanish”:

Conjecture: $\text{SK}_1(D_{k(\text{SL}_1(D))}) = 1$ if and only if the degree of $D$ is square free.

So far, there is just this result:

---

The reason for this is as follows: For an arbitrary ring $R$, one defines the groups $\text{GL}(R) = \lim \text{GL}_n(R), E(R) = \lim \text{E}_n(R)$ as the inductive limits via the embeddings given by $\text{GL}_n(R) \ni a \mapsto \begin{pmatrix} a & 0 \\ 0 & 1 \end{pmatrix} \in \text{GL}_{n+1}(R)$, (here $E_n(R)$ being the group generated by the elementary matrices $1_n + x e_{ij}$). Then $K_1(A) := \text{GL}(R)/E(R)$ is an abelian group.

If $R$ is commutative, then one has as well the inductive limit $\text{SL}(R) = \lim \text{SL}_n(R)$, and the determinant gives an epimorphism $\text{det} : K_1(R) \mapsto R^*$, since $E_n(R) \subset \text{SL}_n(R)$ with the kernel $K_1(R) := \text{SL}(R)/E(A)$. This map splits because of $R^* \cong \text{GL}_1(R) \hookrightarrow \text{GL}(R) \mapsto R^*$, hence we get $K_2(R) = \text{SK}_1(R) \oplus R^*$.

If $R = D$ is a division algebra over a field $k$, and if det is replaced by the reduced norm $\text{RN}$, then $\text{SL}_n(D) \supset E_n(D)$ and the above definitions amount to $K_1(D) = \lim \text{GL}_n(D)/E_n(D)$, $\text{SK}_1(D) = \lim \text{SL}_n(D)/E_n(D)$. From the properties of the Dieudonné determinant we obtain $K_1(D) \cong D^*/[D^*,D^*]$ and $\text{SK}_1(D) = \text{SL}_1(D)/[D^*,D^*]$. 

---

$^4$The reason for this is as follows: For an arbitrary ring $R$, one defines the groups $\text{GL}(R) = \lim \text{GL}_n(R), E(R) = \lim \text{E}_n(R)$ as the inductive limits via the embeddings given by $\text{GL}_n(R) \ni a \mapsto \begin{pmatrix} a & 0 \\ 0 & 1 \end{pmatrix} \in \text{GL}_{n+1}(R)$, (here $E_n(R)$ being the group generated by the elementary matrices $1_n + x e_{ij}$). Then $K_1(A) := \text{GL}(R)/E(R)$ is an abelian group.

If $R$ is commutative, then one has as well the inductive limit $\text{SL}(R) = \lim \text{SL}_n(R)$, and the determinant gives an epimorphism $\text{det} : K_1(R) \mapsto R^*$, since $E_n(R) \subset \text{SL}_n(R)$ with the kernel $K_1(R) := \text{SL}(R)/E(A)$. This map splits because of $R^* \cong \text{GL}_1(R) \hookrightarrow \text{GL}(R) \mapsto R^*$, hence we get $K_2(R) = \text{SK}_1(R) \oplus R^*$.

If $R = D$ is a division algebra over a field $k$, and if det is replaced by the reduced norm $\text{RN}$, then $\text{SL}_n(D) \supset E_n(D)$ and the above definitions amount to $K_1(D) = \lim \text{GL}_n(D)/E_n(D)$, $\text{SK}_1(D) = \lim \text{SL}_n(D)/E_n(D)$. From the properties of the Dieudonné determinant we obtain $K_1(D) \cong D^*/[D^*,D^*]$ and $\text{SK}_1(D) = \text{SL}_1(D)/[D^*,D^*]$. 

---
Theorem 6.6 (Merkurjev, [13]) Let $D$ be a division algebra over a field $k$. If the degree of $D$ is divisible by 4, then $\text{SK}_1(D_{k(\text{SL}_1(D))}) \neq 1$.

In fact, in [13] the assumption was that $\text{char } k \neq 2$, but this has meanwhile been removed.

The main tool in the proof is a theorem by Rost, who had proved an exact sequence $0 \rightarrow \text{SK}_1(D) \rightarrow H^4(F, \mathbb{Z}/2\mathbb{Z}) \rightarrow H^4(F^q, \mathbb{Z}/2\mathbb{Z})$ which compares $\text{SK}_1(D)$ for a tensor product $D$ of two quaternion algebras with the Galois cohomology of a quadratic Albert $q$ form which is related to the two quaternion forms involved.

Further details can be obtained from the Book of Involutions [11], §17.
